

Paget-Schroetter Syndrome

A 34-year-old man, kickboxing, presented on emergency room with 24 hours of sudden onset right upper extremities (RUE) pain, swelling and heat after vigorous exercise with that member, without trauma. He was hemodynamically stable, with RUE edema. Color doppler showed right axillary, subclavian and jugular veins thrombosis. Computed tomographic pulmonary angiography confirmed the findings, associated to acute bilateral pulmonary embolism at the level of the segmental branches (Figure 1 and 2). Excluded secondary causes of venous thrombosis of the upper limb. As described on literature on that season, he completed 6 months with anticoagulation with symptoms resolution.

Paget-Schroetter Syndrome is an effort thrombosis more common in young athletes without significant comorbidities¹. Symptom onset is usually acute or sub-acute and not infrequently can be nonspecific. Color doppler is the least invasive and least costly exam, with adequate sensitivity and specificity for diagnosis. Treatment include anticoagulation with or without revascularization therapy, such as thrombolysis, endovascular or surgical therapy^{2,3}. Complications include pulmonary embolism, present at 3% of effort thrombosis⁴. However, irrespective of the relative risk, the risk of pulmonary embolism with effort thrombosis is real and significant⁵. It's a clinical condition with impact on the patient's quality of life.

Fig. 1. Computed tomographic pulmonary angiography showed right axillary, subclavian and jugular veins thrombosis (red arrows).

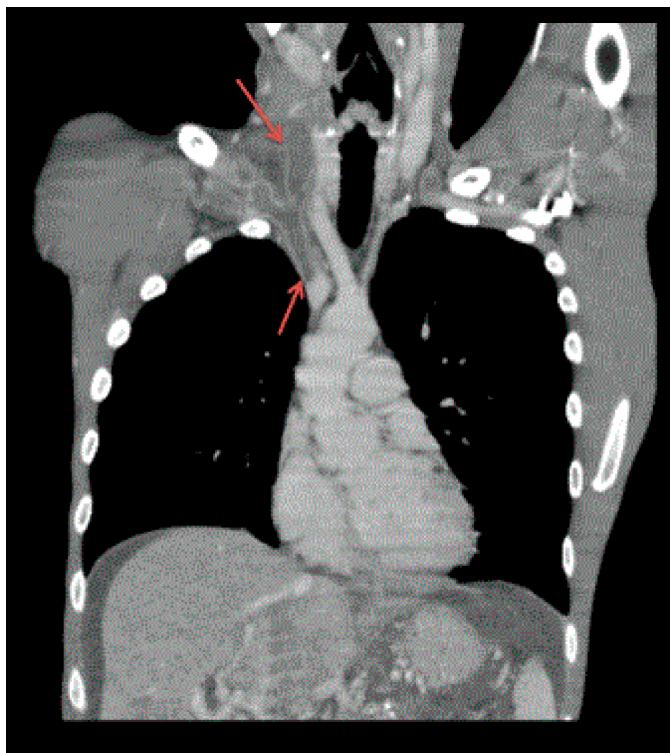

Fig. 2. Computed tomographic pulmonary angiography with different views. We can see right axillary, subclavian and jugular veins thrombosis (A, B, C), started on origin of subclavian vein (d) and pulmonary embolism (E).
