TRADE POLICY VERSUS INSTITUTIONAL TRADE BARRIERS: AN APPLICATION USING “GOOD OLD” OLS

Laura Márquez-Ramos*

Abstract

Trade policy barriers are only one element of overall trade costs. Due to the decrease in the influence of tariff barriers on trade over time, institutional barriers are increasing in relative importance. This paper quantifies and compares the impact that a number of institutional and policy trade barriers have on bilateral trade flows. A theoretically justified gravity model of trade is estimated by using Baier and Bergstrand (2009) proposed methodology for a cross-section of countries in 2000. Results indicate that institutional trade barriers have a greater impact on trade flows than tariff barriers. According to these findings, trade policy negotiation efforts should focus on facilitating trade processes and should be at the forefront of multilateral negotiations.

Keywords: Tariff barriers, trade facilitation, sectoral trade.

JEL classification: F14.

1. Introduction

In the last decades, trends towards geographical regionalisation and globalisation have led to a decrease in the influence of tariff barriers on trade¹. Indeed, in 1987, the overall annual average applied tariff rate (expressed in non-weighted terms) was of 25%, whereas in 2007 this figure was only 9%². As a consequence, other trade costs components such as transport costs and technological innovation have gained importance as determinants of trade patterns worldwide. Indeed, a broader concept named “trade facilitation” is of growing interest in the trade policy debate and has been explicitly included in the Doha Development Agenda.

Whereas the role of tariffs in trade has a long tradition (see e.g. Kreinin, 1961; Harrigan, 1993), as well as the role of technological innovation (see e.g. Vernon, 1970; Soete, 1987; Freund and Weinhold, 2004; Fink et al., 2005). It has been only recently that a number of studies have examined the importance of trade facilitation (Wilson et al., 2005; Djankov, Freund and Pham, 2006; Martínez-Zarzoso and Márquez-Ramos, 2008). In earlier studies, the usual approach was to focus on only one of the abovementioned trade determinants, instead of considering simultaneously the effect of the different components of trade costs. More recently, a few studies have considered in a single investigation different components of trade costs. Examples are Baier and Bergstrand (2001) who explained the growth of world trade with transport costs, tariffs and income variables and van Wincoop (2004) who specifically studied the different components of trade cost and their trade effects and presented an extensive review of the empirical literature.

From a methodological point of view, a growing number of studies use the gravity model of trade as a general framework to estimate the determinants of bilateral trade flows. However, only the most recent research solves some of the estimation problems related to the correct specification of the so-called multilateral resistance terms. Anderson and van Wincoop (2003) show that it is not just bilateral trade costs, but those costs relative to multilateral trade cost that are relevant for predicting bilateral trade. Omitting controls for the so-called multilateral resistance can lead to biased coefficient estimates. More importantly, it can lead to grossly misleading comparative static estimates of the impact of trade barriers on trade.

This paper aims to contribute to the existent literature in three fronts. First, it aims to quantify and compare the effect of tariff barriers, technological innovation and trade facilitation measures on international trade flows at sectoral level. We consider the role of tariffs, internal transport cost, time required to cross borders and number of documents required for trade, together with information technology, as influential factors in disaggregated trade flows. Secondly, it uses a new methodology, recently developed by Baier and Bergstrand (2009) suitable to construct multilateral resistance terms for all bilateral variables and include importer-equivalents for all

¹ Trade policy can still be a key issue in some countries. For example, tariff peaks and tariff escalation remain important issues for developing countries.

² See Figure A.1 in the Appendix.

country-specific variables. The advantage of this method over the traditional log-linear OLS approach is that it is based on a theoretically grounded gravity model. Finally, as there are clear economic differences between developed and developing countries leading to disparities in the impact that the determinants of bilateral trade flows have on trade, the model will be estimated separately for each exporter.

The main results can be summarised as follows. Firstly, a reduction in the number of days and the number of documents needed for trade promotes international trade to a greater extent than equivalent reductions in tariff barriers. Secondly, the former effect is comparable to the effect of distance on trade. Finally, information technology also plays an important role in promoting trade. The paper is organised as follows. Literature review about trade facilitation and methodology used in the present paper is outlined in Section 2. In Section 3, the data, sources and variables used are presented, together with a detailed description of how the trade facilitation and tariff data were gathered. Section 4 presents the model specification, the main results and a number of robustness tests. Simulations and policy implications are presented in Section 5. Finally, Section 6 offers some concluding remarks.

2. Literature Review

In this section we mainly review the recent literature related to trade facilitation in a very broad sense, including information technology as one of the factors that facilitate trade. But, since we also consider the effect of tariffs, we consider appropriate to briefly refer to the literature on the effects of trade policy barriers on imports. Harrigan (1993) is probably the paper most related to our investigation. The author develops a monopolistic competition model to evaluate the effect of trade barriers on OECD imports. In his model, transport costs are also included as a determinant of trade and trade policy barriers are divided into tariffs and non-tariff barriers (NTBs). In his empirical evaluation of the theoretical model, estimated for a cross-section of 13 OECD countries and 28 product categories using data for 1983, he concludes that estimated transport costs and average tariffs had large negative effects on imports, although the level of tariffs was generally low. In contrast, NTBs had a small or imperceptible effect on gross imports.

Moving now to trade facilitation, the issue is clearly gaining interest in the trade policy debate, as shown by its inclusion in the Doha Development Agenda. However, the measurement and quantification of the potential benefits of trade facilitation have only recently been investigated and the approaches used are far from uniform in terms of the definition of trade facilitation and the empirical approach used.

In relation to the definition of trade facilitation, Wilson, Mann and Otsuki (2003, 2005) considered a broad definition of trade facilitation, and quantified the impact of four different measures (port efficiency, customs environment, regulatory environment and e-business usage). As an alternative, Engman (2005) used the WTO definition of trade facilitation (the simplification and

harmonisation of international trade procedures) by paying attention only to what happens around the border. Other authors³ focused, instead, on the effects of single measures of trade facilitation (information technology, port efficiency, institutions' quality).

Two main modelling approaches have been used. On the one hand, several investigations use the gravity model of trade augmented with "trade facilitation" variables. In this line, Wilson, Mann and Otsuki (2003, 2005) estimated a gravity model of trade augmented with the above-mentioned trade-facilitation variables for a group of countries in the Asia-Pacific region and for a sample of 75 countries. In addition, Soloaga, Wilson and Mejía (2006) used a similar methodology and data, but focused on Mexican competitiveness. In a more general setting, Djankov, Freund and Pham (2006) used the World Bank's Doing Business Database, as we do in this paper, but focused only on the effects of time delays in the exporting country whereas Nordas, Pinali and Grosso (2006) centred on how time delays affect the probability to export and the export volumes for imports from Japan, Australia and the United Kingdom. Persson (2007) studied the effect of time delays and transaction costs on trade flows using a sample selection approach and focussing on the specific effects for each of the six groups of ACP countries negotiating Economic Partnership agreements with the EU. Finally, Martínez-Zarzoso and Márquez-Ramos (2008) analyse the effect of trade facilitation on trade volumes at a disaggregated level. They focus on the simplification of "at the border procedures", which include the number of documents and amount of time involved in border crossings, as well as the transaction cost incurred. Their results support multilateral initiatives that encourage countries to assess and improve their trade facilitation needs and priorities.⁴

On the other hand, several institutions and authors (UNCTAD, 2001; OECD, 2003; Dennis, 2006; Decreux and Fontagne, 2006) used a computable general equilibrium model to estimate the effect of a composite index of trade facilitation on trade flows.

Although several data sets and estimation methods have been utilised within the context of these two approaches, the results reveal significant and positive effects on trade flows in most cases.

This paper mainly differs from existing literature in that it compares the effectiveness of several trade facilitation measures with the effectiveness of trade liberalisation, in the inclusion of three different measures of trade facilitation for exporter and importer countries and in the improvement of the methodological approach.

3. Data, sources and variables

Bilateral trade data by commodity were obtained from Feenstra et al. (2005). The level of disaggregation chosen was the 4-digit SITC. The sample of countries comprised 13 exporters

³ See Wilson, Mann and Otsuki (2003, 2005) for a more detailed review of earlier work on single measures of trade facilitation.

⁴ Arruñada (2007) states that the priority should not only be to simplify the procedures, but also, to restructure formalities and enhance the value of institutions to generate reliable information, which is essential for reducing transaction costs.

and 167 importers in the year 2000 (Table A.1, Appendix). The 13 exporters were chosen to have a representative sample of the world economy in accordance to the classification matrix constructed in Martínez-Zarzoso and Márquez-Ramos (2008). The sectors analysed include 146 sectors with homogeneous goods, 349 sectors with reference-priced goods, and 694 sectors with differentiated goods.

The databases used to construct the explanatory variables for the regression analysis are the World Development Indicators (2005) for income and the Doing Business (2006) database for trade facilitation variables. This database was recently created by the World Bank and it compiles procedural requirements for exporting and importing a standardised cargo of goods. Data are for 2004. Distance between capitals is taken from CEPII.⁵ Technological innovation is proxied using the Technological Achievement Index (TAI) computed by UNDP (2001), which is only available for 2000. This indicator takes into account a broad array of variables related to technological innovation.

Tariff data come from the Trade Analysis Information System (TRAINS) and were extracted using WITS (World Integrated Trade Solution). Tariffs faced by each of the 13 exporting countries were collected by using the importing countries as reporting countries. We obtained tariffs weighted by their corresponding trade values at one digit SITC level in the year 2000. TRAINS presents three types of tariff for each product: bound rate, preferential and Most-Favoured Nation tariffs (MFN). Bound tariffs are specific commitments made by individual WTO members. The bound rate is the maximum MFN tariff level for a given product line. When WTO members negotiate tariff levels, they agree the bound tariff rates, but these are not necessarily the same rates that a WTO member applies to other WTO members' products.⁶ The preferential rate is the lowest one. Under a preferential trade agreement, one country imposes lower tariffs on another country's products than their MFN rate. Exporting countries may therefore have access to several different preference programmes from a given importing partner and for a given product. MFN tariffs are the rate countries promise to impose on imports from other members of the World Trade Organisation, unless the country is part of a preferential trade agreement.

WITS uses the concept of effectively applied tariffs, defined as the lowest tariff granted by an importer to an exporter for a particular product.⁷ The rates used in this paper are the weighted average effectively applied tariffs for each country importing each product from the 13 exporters in the sample. Table 1 shows weighted average tariffs imposed on imports from the 13-country

⁵ The dist_cepii file was taken from <http://www.cepii.fr/anglaisgraph/bdd/distances.htm>. Simple distances are calculated following the great circle formula, which uses the latitudes and longitudes of the most important cities/agglomerations (in terms of population).

⁶ Countries can break a commitment (i.e. raise a tariff above the bound rate), but only with difficulty. To do so they have to negotiate with the countries most closely concerned and that could result in compensation for trading partners' loss of trade.

⁷ UNCTAD and the World Bank have computed ad valorem equivalents (AVEs) of non ad valorem tariffs, which are included when average tariff rates are computed. A three-step method for estimating unit values is used: (1) from tariff line import statistics of the market country available in TRAINS; then (if (1) is not available) (2) from the HS 6-digit import statistics of the market country from COMTRADE; then (if (1) and (2) are not available) (3) from the HS 6-digit import statistics of all OECD countries. Once a unit value is estimated, then it is used for all types of rates (MFN, preferential...).

sample to all importing countries in the year 2000 for the different sections of the Standard International Trade Classification (SITC, revision 2). Overall, protection is greater on sensitive products such as food and live animals, beverages and tobacco and animal and vegetable oils, fats and waxes.

Trade facilitation variables are from the Doing Business Dataset. It compiles the procedural requirements for exporting and importing a standardised cargo of goods. Every official procedure for exporting and importing the goods is recorded (from the contractual agreement between the two parties to the delivery of goods) along with the time and cost necessary for completion. All documents required for the clearance of the goods across the border are also recorded. For exporting goods, procedures range from packing the goods at the factory to their departure from the port of origin. For importing goods, procedures range from the vessel's arrival at the port of entry to the delivery of the cargo to the factory warehouse. Local freight forwarders, shipping lines, customs brokers and port officials provide information on required documents and costs, as well as the time for completing each procedure. To make the data comparable across countries, several assumptions about the business and the traded goods are made. The main assumptions refer to the business and types of goods traded. The business has to be located in the country's most populous city, and it must have 200 employees or more. It is assumed to be a private, limited liability company that does not operate within an export processing zone, or an industrial estate with special export or import privileges. The business must be domestically owned with no foreign ownership and must export more than 10% of its sales.

The traded product must travel in a dry-cargo, 20-foot, full container load, not be hazardous, and not include military items. In addition, it must not require special conditions for transport, like refrigeration, and must not require any special plant health or environmental safety standards other than accepted international standards. Finally, the product falls under the following Standard International Trade Classification (SITC) Revision categories: SITC 65 (textile yarn, fabrics and made-up articles); SITC 84 (articles of apparel and clothing accessories) or SITC 07 (coffee, tea, cocoa, spices and manufactures thereof).

The inland transport cost is recorded as the fees levied on a 20-foot container in US dollars. All the fees associated with completing the procedures to export or import goods are included. These, in turn, include costs of documents, administrative fees for customs clearance and technical control, terminal handling charges and inland transport. The cost measurement does not include tariffs or trade taxes. Only official costs are recorded.

The first half of Table 2 shows summary statistics of the variables used in the empirical application and the second half shows the simple correlations among the variables used.

4. Empirical analysis

4.1. Model specification

The empirical strategy is based on the gravity model of trade. The impressive goodness of fit of the gravity model applied to bilateral trade flows is widely recognised. Some authors have referred to this model as the “workhorse” of empirical trade studies (Eichengreen and Irwin, 1998; Cheng and Wall, 2005). In the context of the gravity model, Anderson and van Wincoop (2003) emphasise the dependence of trade on a bilateral and multilateral resistance factor. These authors refer to price indices as “multilateral resistance” variables that depend on all bilateral resistances, including those that do not directly involve the exporting country.

The theoretical background for our study is provided by the model of Baier and Bergstrand (2009). This model is a generalisation of previous work on the gravity equation, in which special attention is given to modelling the so-called “multilateral resistance” terms (MR). Baier and Bergstrand (2009) demonstrated that a first-order log-linear Taylor series expansion of the

nonlinear system of price equations provides an alternative OLS log-linear specification that introduces theoretically motivated MR. This methodology has two basic advantages with respect to the other approaches recently proposed to estimate a “theoretically motivated” gravity equation. Firstly, it is simpler than the custom nonlinear least squares (CNLS) program proposed by Anderson and van Wincoop (2003), which has scarcely been applied by empirical researchers. Secondly, it enables the comparative static effects of a trade costs to be estimated. The most commonly applied approach to estimate potentially unbiased gravity equation coefficients since Anderson and van Wincoop (2003) is to use region-specific fixed effects, as already suggested by the authors and by Feenstra (2004). Although this method is very simple and avoids the measurement error associated with measuring regions’ “internal distances” (as in CNLS), it does not allow estimation of the comparative static effects of trade costs. Moreover, the Anderson and van Wincoop (2003) approach is only valid in a world with symmetrical bilateral trade costs ($t_{ij}=t_{ji}$), whereas the MR approximation terms also work under asymmetrical bilateral trade costs.⁸ Baier and Bergstrand (2009) suggest applying a first-order Taylor expansion to the explanatory variables and estimating the gravity model specified with the transformed variables using OLS. By using this methodology, the independent variables are transformed as follows:

$$(x_{ijk})_{P_i P_j} = \frac{1}{N_i} \sum_{i=1}^{N_i} x_{irk} + \frac{1}{N_j} \sum_{j=1}^{N_j} x_{jsk} - \frac{1}{N_i} \sum_{i=1}^{N_i} x_{irk} \frac{1}{N_j} \sum_{j=1}^{N_j} x_{jsk} \quad (1)$$

$$(x_{ik} x_{jk})_{P_i P_j} = \frac{1}{N_i} \sum_{i=1}^{N_i} x_{ik} + \frac{1}{N_j} \sum_{j=1}^{N_j} x_{jk} - \frac{1}{N_i} \sum_{i=1}^{N_i} x_{ik} \frac{1}{N_j} \sum_{j=1}^{N_j} x_{jk} \quad (2)$$

where r is an index of the country partners of i and s is an index of the country partners of j. Equation (1) refers to variables with bilateral variability (e.g. distance), whereas Equation (2) indicates the transformation required for variables with country or sectoral variability, but which are common for all the trading partners. The estimated equation is:

$$\begin{aligned} \ln X_{ijk} = & \alpha_0 + \alpha_1 \ln(Y_i Y_j)_{P_i P_j} + \alpha_2 (\ln Dist_{ij} - \ln Dist_{P_i P_j}) + \\ & + \alpha_3 (\ln Tariffs_{ijk} - \ln Tariffs_{P_i P_j}) + \alpha_4 (\ln ET_i \ln ET_j)_{P_i P_j} + \varepsilon_{ijk} \end{aligned} \quad (3)$$

where \ln denotes natural logarithms. X_{ijk} denotes the value of exports of commodity k from country i to country j ; Y_i and Y_j are incomes in the origin and destination market respectively; $Dist_{ij}$ is the geographical great circle distance in kilometres between the most important cities (in terms of population) of countries i and j . $Tariff_{ijk}$ is the weighted average effectively applied tariff for each

⁸ See Addendum to “Bonus Vetus OLS” (B-B, 2007) in http://www.nd.edu/~jbergstr/working_papers.html.

country importing each commodity from the 13 exporters.⁹ ET_i and ET_j are easy-to-trade variables (technological innovation, internal transport costs, time and number of documents required to trade) for the exporting and importing country respectively. Technological innovation is measured as the product of the Technological Achievement Index (TAI) of countries i and j , internal transport costs is measured as the product of the fees levied on a 20-foot container in US dollars in countries i and j . All the fees associated with completing the procedures to export or import goods are included. Documents is measured as the product of the number of documents required to trade in countries i and j . Finally, ε_{ijk} is the error term, which is assumed to be independently and identically distributed.

4.2. Main results

Table 3 shows the results obtained for the full sample. Note that due to the complementarity of the ET variables considered, models 1-4 include separately each trade facilitation variable, namely technological innovation, transport costs, number of days and number of documents required to trade, respectively. In order to improve the measure of ET, we also computed an average ET that is calculated as the simple average of the transformed variables:

$$\sum_{m=1}^3 (x_{ik} x_{jk})_{P_i P_j} / 3, \text{ where } x \text{ denotes time, internal transport costs and number of documents. The}$$

results obtained when including this variable are shown in Table 5.

Tariff barriers are negative and significant, as expected, although the coefficients obtained for trade facilitation variables are higher. On one hand, technological innovation is positive and significant, indicating that improving service infrastructure fosters international trade. On the other hand, inland transport costs, the number of documents and days required to export deter international trade flows. This deterrent effect is greater for variables related to bureaucratic procedures and waiting time at the border than for internal transport costs. Additionally, our results show the expected negative effect of distance on trade.

These results were similar to those found in the estimates with exporter and importer fixed effects. In particular, the elasticity for distance was -0.54 (0.006), for tariff barriers was -0.02 (0.001) and for time delays was -0.32 (0.06).¹⁰

Since each variable is measured in different units, we calculate beta coefficients to be able to compare the magnitude of the effects in terms of standard deviations. The beta coefficients are shown in Table A.2 in the Appendix. The highest beta coefficients are, in absolute value, for distance, income and some trade facilitation variables, especially time to trade, technological innovation and number of documents whereas tariff barriers and internal transport costs show lower beta coefficients. These results indicate that trade facilitation variables play a more

⁹ This variable is disaggregated at 1 digit level (SITC classification).

¹⁰ Robust standard errors in brackets.

important role as determinants of trade patterns than do tariff barriers. The interpretation is as follows. For example, changing the time to trade by one standard deviation, holding constant the other explanatory variables, would increase exports by 0.17 standard deviations, whereas the effect of a reduction of the average distance by one standard deviation would increase exports by 0.2 standard deviations. Thus we can conclude that a change in distance has a slightly greater relative effect on exports than does a change in time to trade.

Finally, with respect to the goodness of fit of the model, the R squared indicates that the model is able to explain only around twenty percent of the variability of sectoral exports. This low explanatory power, in comparison to the high explanatory power of the model when aggregated trade data are used is common to other gravity model estimations using disaggregated data.

Data is for the year 2000.

4.3. Robustness

In this section we present estimates of the extended gravity model for different exporters and different types of goods to account for possible sources of heterogeneity in the sample.

4.3.1. The effect of tariff barriers and trade facilitation measures on imports from different countries

The level of protection for goods coming from developing countries face lower average weighted tariffs in developed countries than in developing countries; however, developing countries face higher tariffs in developed countries than those applied to developed countries trading among themselves (Table A.3). Average weighted tariffs equal to zero are more frequent among developed countries. Indeed, the second part of Table A.3 shows that the mean of the effectively applied weighted tariffs among developed countries is 4.5%, while it is much higher when one (or both) of the trading partners is a developing country (10.6%). This phenomenon is known as “tariff bias” against developing countries.

To focus on the effect of trade barriers on imports from different countries, we estimate a separate regression for each of the 13 exporters included in the sample. We analyse the extent to which imports from developed and developing countries are deterred by tariffs and by trade facilitation barriers.

Results of estimating equation (3) are shown in Table 3. With respect to the trade facilitation variables, 85% of the estimated coefficients present the expected sign. UK, Germany and China exports face the largest elasticity with respect to number of documents needed to trade. A possible explanation could be that more complicated procedures are required for goods coming from larger exporters whose exports are very competitive, as a means of deterring stronger competitors from accessing the market.

Overall, trade facilitation variables are of greater importance than tariff barriers. Tariffs present higher elasticity for goods exported from the United States, Australia, Germany and South Africa, whereas for Brazil, Chile, Ghana and Japan this variable is non-significant.

Additionally, the magnitude of the coefficient of the inland transport cost variable for exporters located far away from the main markets (Australia, China and Japan) is considerably higher than the average value obtained in Table 3. As the transport cost variable includes only internal transport costs, and we control for distance in the model, the question that arises is why products exported from Australia, China and Japan face greater elasticity with respect to internal transport costs. A possible explanation is that importers easily can substitute goods coming from those locations with goods coming from closer exporters with lower internal transport costs.

Otherwise, results obtained for middle-income and low-income countries such as Bolivia, Brazil, Chile, Czech Republic and Ghana are less robust. Trade facilitation variables are not significant in a number of cases (Chile, Ghana) or do not show the expected sign (Bolivia, Czech Republic). This result could be due to the reduced size of the sample or to the importance of other factors, such as exchange rates or infrastructures, which could be the main determinants of exports in developing countries.

Table 4. Determinants of exports from each of the 13 exporting countries.

Notes: ***, **, * indicate significance at 1%, 5% and 10%, respectively. T-statistics are given in brackets. All regressions include income and distance variables, the coefficients are not reported to save space. The dependent variable is the natural logarithm of exports in value (thousands of \$US) of commodity k from country i to j. The estimation uses White's heteroscedasticity-consistent standard errors. Data is for the year 2000. Number of observations, R-squared and RMSE correspond to regression including technological innovation as a trade facilitation measure.

4.3.2. The effect of tariff barriers and trade facilitation measures in different sectors

In this section, the effects of trade barriers and trade facilitation variables on trade for different sectors are analysed and compared. Two classifications are considered. Firstly, the model is estimated for differentiated, reference-priced and homogeneous goods according to the Rauch classification. High-technology goods, as defined in the OECD (2001) and Eurostat (1999) classifications are also considered as a separate category.¹¹ Secondly, the model is estimated for each of the sections of the SITC (Sections 0-9)¹². Table 5 shows the main results.

When Rauch's classification and high-technology sectors are considered, results show that trade facilitation improvements would benefit differentiated, reference-priced and high-technology

¹¹ The list of high-technology sectors considered to create the technology dummy is available upon request from the authors.

¹² See Table A.4 in the Appendix for a description of each Section.

products to a greater extent than homogeneous goods. This result is in line with the assumption that the search model developed by Rauch (1999) applies most strongly to differentiated products and most weakly to products traded on organised exchanges. Hence, trade facilitation variables should have the greatest effects on matching international buyers and sellers of differentiated products, and search costs should act as the greatest barrier to trade in differentiated products.

In relation to the second classification, the coefficient of tariffs is negative and significant (excluding Sections 2 and 9) and shows elasticity between -0.01 and -0.05. According to the results obtained, the greatest tariff elasticities are found in sensitive products such as food and live animals; mineral fuels, lubricants and related materials; and animal and vegetable oils, fats and waxes. These results can be compared with those obtained by other authors. For example, Fink et al. (2005) also estimate a sectoral gravity equation using trade flows classified according to Rauch classification. These authors find that the estimated coefficient for the tariff variable is not statistically different from zero in the case of differentiated goods, whereas it is negative and statistically significant in the case of reference-priced and homogeneous goods. Along the same lines, Tang (2006) analyses the factors that contribute to the growth of US imports in differentiated, reference-priced and homogeneous goods. Although US tariffs on differentiated goods were reduced by 2.25% in the period 1975-2000, this reduction explains only 0.2% of the growth in US imports of differentiated goods. Meanwhile, the contribution of decreasing tariff barriers to the growth of US imports is about 8% for reference-priced and 13.7% for homogeneous goods. Tariff barriers therefore play a more important role for trade in reference-priced and homogeneous goods.

In relation to trade facilitation variables, results show that improvements in service infrastructure (measured as countries' technological achievement), and reducing the number of days and documents required for trade are of greater importance than internal transport costs (which include all the official fees associated with completing the procedures to export or import goods). Nonetheless, transport costs play an important role in the case of trade of goods included in Section 8 and high-technology goods.

Data is for the year 2000. Number of observations, R-squared and RMSE correspond to regression including technological innovation as a trade facilitation measure.

5. Simulations and policy implications

Using the estimated elasticities presented in Table 4, we are able to simulate the increase in exports for several countries derived from taking the country to the sample average. China, Germany, Japan, the United Kingdom and the United States are the exporting countries considered in the simulations since they present the most robust results. Table 6 presents the increase in exports associated to reductions in the cost to import, in the days, and documents needed to import in those countries with trade facilitation measures above the sample average. Simulations are presented for several groups of importers: low-income, middle-income, high-income non-OECD and high-income OECD countries.

Columns (1), (4) and (7) show the average cost to import, time for import and number of documents for import in low-income, middle-income, high-income non-OECD and high-income OECD countries, respectively. Columns (2), (5) and (8) show the percentage reduction necessary to take the group of countries to the sample average. Finally, columns (3), (6) and (9) show the

changes in trade flows for different exporters derived from taking the importing economic regions to the sample average.

Then, Table 6 presents the increase in trade flows which would take place if the importing countries were to reduce the cost, time and documents to the sample average. For example, if low-income countries were to reduce the average days for imports to the average (the reduction needed would be of 55%),¹³ exports from China would increase by 33%. Overall, results show that Asian countries (China and Japan) would increase their exports to a higher extent if the cost to import in middle-income countries would be reduced to the sample average. Otherwise, the European countries considered (Germany and the United Kingdom) and the United States would benefit the most, in terms of increasing exports, if low-income and middle-income were to reduce the average days for imports to the average. Moreover, all the exporters considered would increase exports considerably if high-income non-OECD countries would reduce their number of documents needed to import and if high-income OECD countries would reduce their cost to import.

¹³ This percentage changes since it is calculated as the simple average of trade facilitation measures in countries importing from China, Germany, Japan, the United Kingdom and the United States, which export to different destinations.

Table 6. Changes in trade flows with improvement in cost, days and documents at the border.

	High Income OECD	1228	-16.88	10.63	16.86	-	-	7.86	-	-
UK	Low Income	2394.37	-48.34	11.6	65.03	-58.73	31.72	13.46	-34.44	24.45
	Middle Income	1729.08	-30.26	7.26	34.03	-17.16	9.27	9.77	-7.77	5.52
	High Inc. Non-OECD	1138.5	-5.52	1.33	25.5	-11.8	6.37	11	-26.48	18.8
	High Income OECD	1301.2	-16.92	4.06	19.2	-	-	8.4	-	-
USA	Low Income	2394.37	-51.68	12.4	65.03	-62.45	23.11	13.46	-36.97	15.9
	Middle Income	1637.56	-30.62	7.35	33.64	-25.16	9.31	9.64	-10.49	4.51
	High Inc. Non-OECD	1138.5	-11.65	2.8	25.5	-19.74	7.3	11	-29.32	12.61
	High Income OECD	1228	-17.02	4.08	16.86	-	-	7.86	-	-

Note: The elasticities used for the simulations are the simple average coefficient obtained in Table 4 for China, Germany, Japan, the United Kingdom and the United States: -0.38 for transport costs, -0.52 for time to trade and -0.58 for documents to trade. Empty cells indicate trade facilitation measures that are below the sample average.

6. Conclusions

In this paper, the effect of reducing trade barriers is analysed and compared with the effect of improving trade facilitation using sectoral data, since disaggregation allows a more accurate analysis of policies for different products. Time, number of documents and cost of trade, as well as information technology achievements are used as proxies for trade facilitation, while tariffs are measured as the weighted average effectively applied tariffs for each country importing each product from the 13 exporters in the sample.

Overall, the main results indicate that trade facilitation variables are, in relative terms, much more important than tariffs, and this result is also obtained for specific countries and sectors. The single-exporter regressions indicate that our model performs better for developed countries than for developing exporters, for which other factors, such as exchange rates, market access or infrastructures, could be the main determinants of exports.

The results for specific types of goods indicate that trade facilitation improvements would benefit trade in differentiated and high-technology sectors to a greater extent than trade in homogeneous goods, basically due to the different weight of fixed costs that both groups of products are assuming.

Finally, some simulations show that China and Japan would increase their exports significantly if the cost to import in middle-income countries would be reduced to the sample average, whereas Germany, the United Kingdom and the United States would benefit the most, in terms of increasing exports, if low-income and middle-income were to reduce the average days for imports to the sample average. According to these findings, trade policy negotiation efforts should focus on facilitating trade processes and should be at the forefront of multilateral negotiations.
